

# CS171: Cryptography

Lecture 8

Sanjam Garg

# Block Ciphers

# Block Ciphers: Recall

- Keyed Permutation

$$F: \{0,1\}^n \times \{0,1\}^\ell \rightarrow \{0,1\}^\ell$$

- $n$  is the key length and  $\ell$  is the block length
- Security:  $F$  should be indistinguishable from a uniform permutation over  $\{0,1\}^\ell$ .
  - Typically, want strong security.
- Interested in concrete security. For key of length  $n$ , security is desired against attacker running in time  $2^n$ .

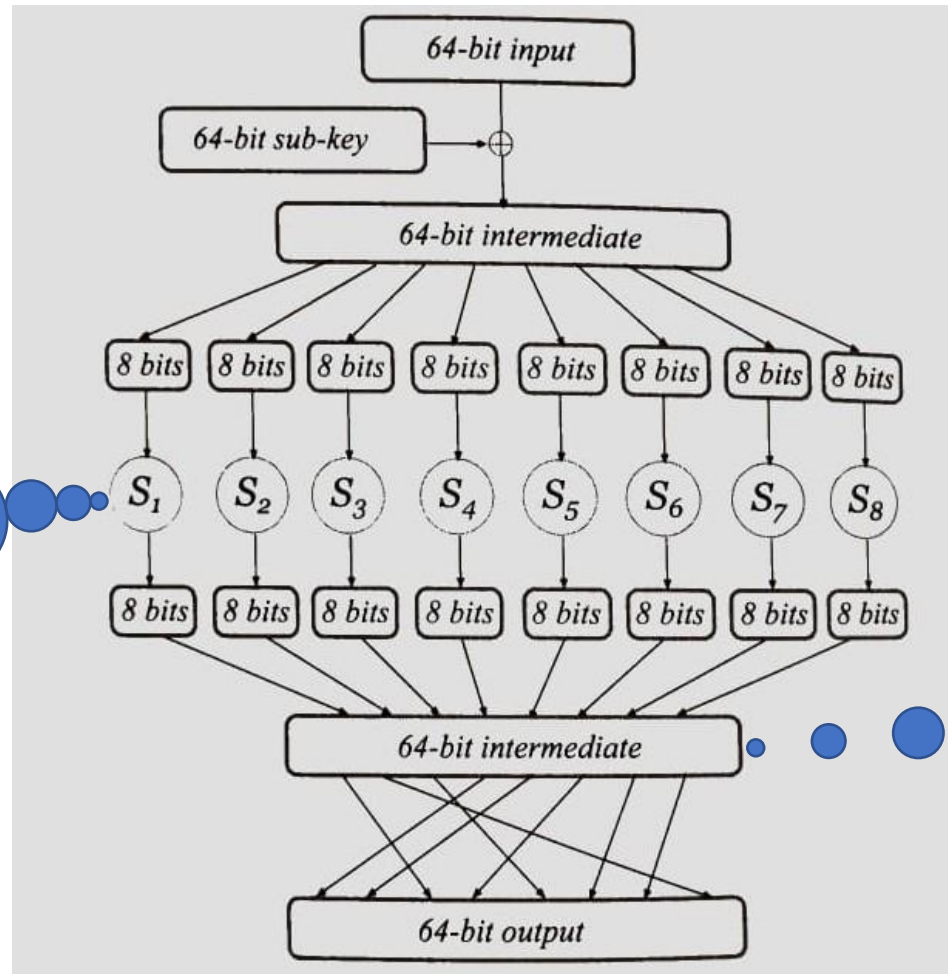

# Challenge involved

- $F$  should be indistinguishable from a uniform permutation over  $\{0,1\}^\ell$ .
- If inputs  $x$  and  $x'$  differ in one bit then what relation between  $F_k(x)$  and  $F_k(x')$  can we expect?
  - How many bits do we expect to change?
  - Which bits do we expect to change?

# Design Paradigms

- Substitution-permutation networks (SPNs)
- Feistel networks

# Add Mixing Permutation

Replace  
Random  
permutations  
with S-boxes!

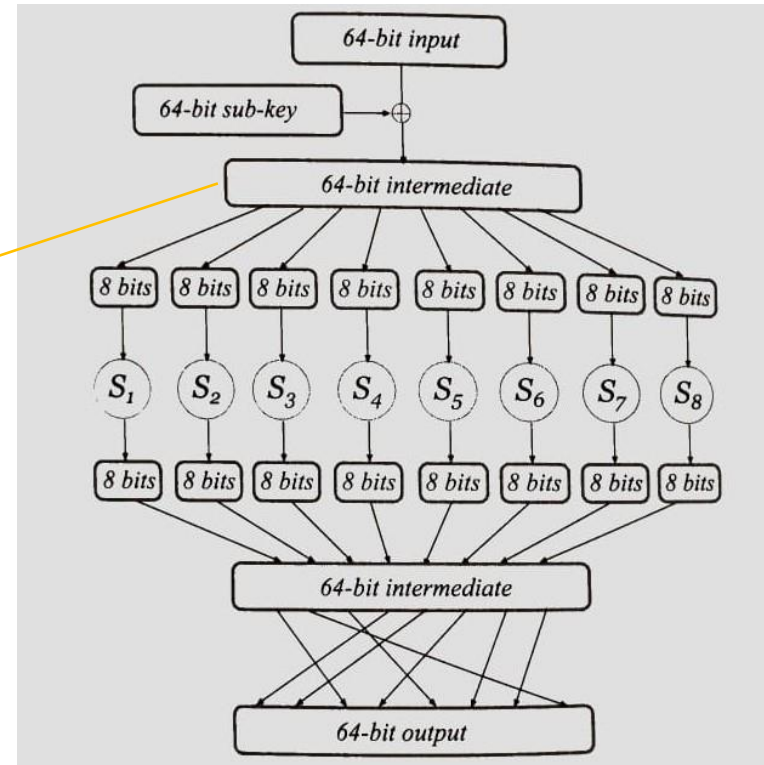

Invertible!

Public Mixing  
Permutation!

# Attacking 1-Round SPN (no output key mixing)

- One Round SPN

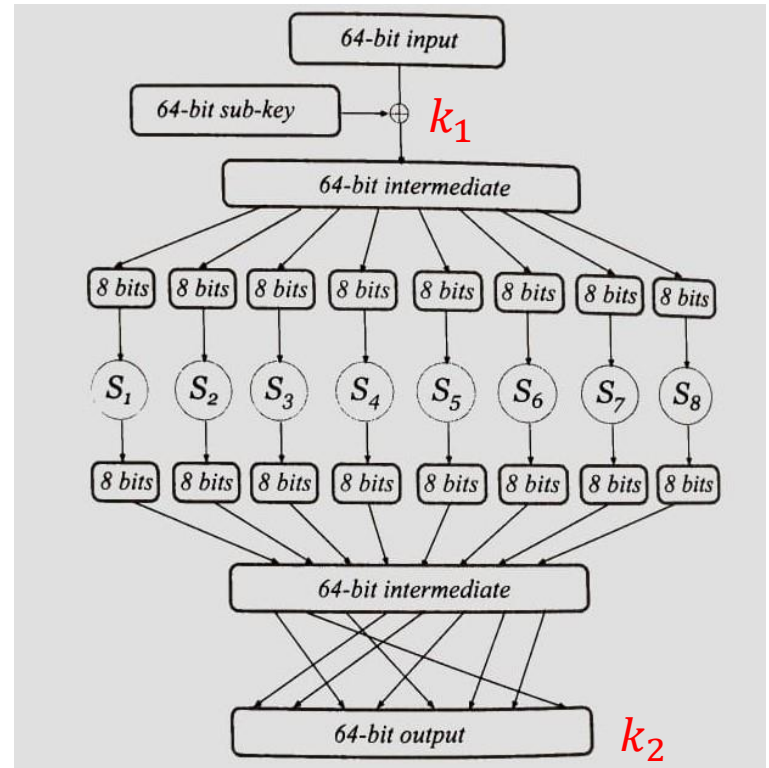

Compute  $z$

- Find  $k$  given  $x, y$ , where  $y = F_k(x)$ ?
- $k = x \oplus z$

# Attacking 1-Round SPN (with output key mixing)

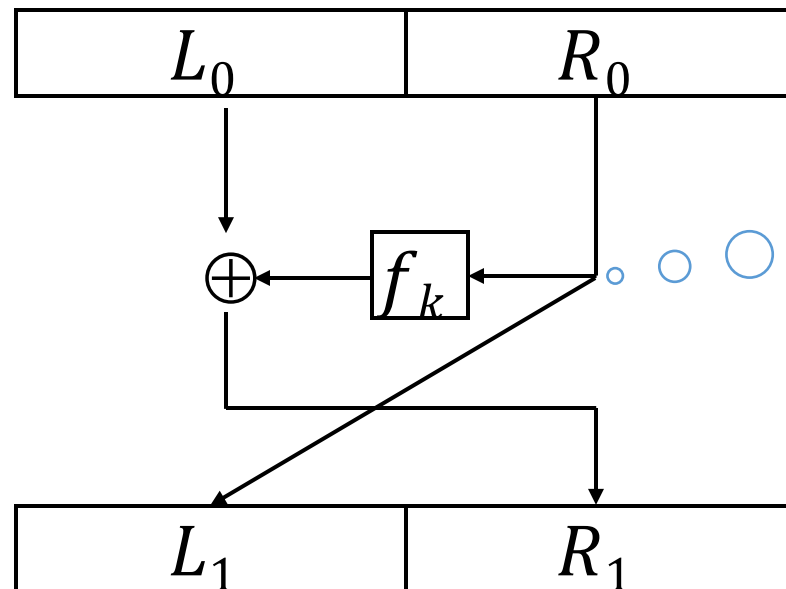

- Find  $k = (k_1, k_2)$
- $\forall k_1$  there is a unique  $k_2$ .
- Running time?
  - $\approx 2^{64}$
- Can we have a better attack?
- Same attack: S-box by S-box!
- Running time?
  - $\approx 8 \cdot 2^8$

# Feistel Networks

- In SPNs, the starting components were *invertible*.
- In Feistel Networks, we build **invertible permutations** starting from **non-invertible** components

Invertible even  
when  $f_k$  is not  
invertible

# Security:

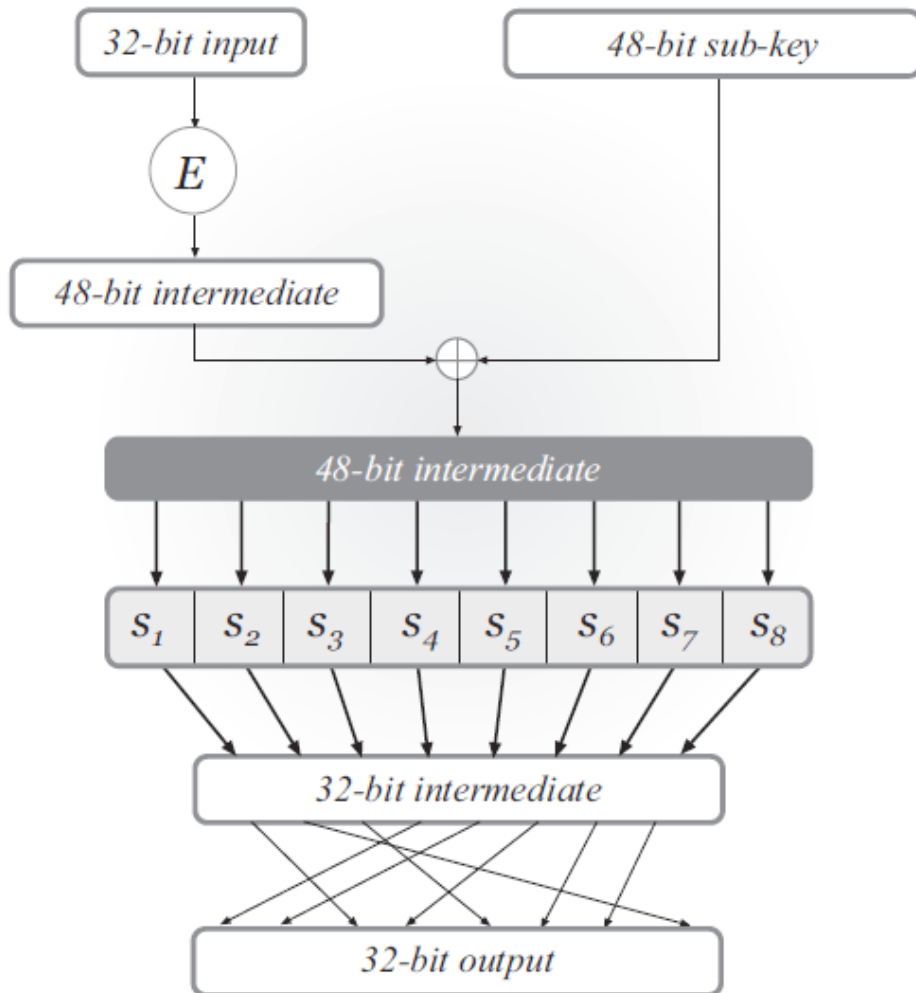

- Is 1 round secure?
  - No! Observe correlations between computations on  $(L_0, R_0)$  and  $(L_0', R_0)$
- Is 2 round secure?
  - No! Compute on  $(L_0, R_0)$  and  $(L_0', R_0)$
  - $L_0$  and  $L_0'$  differ in one bit
- Need 3 or more rounds

# The Data Encryption Standard

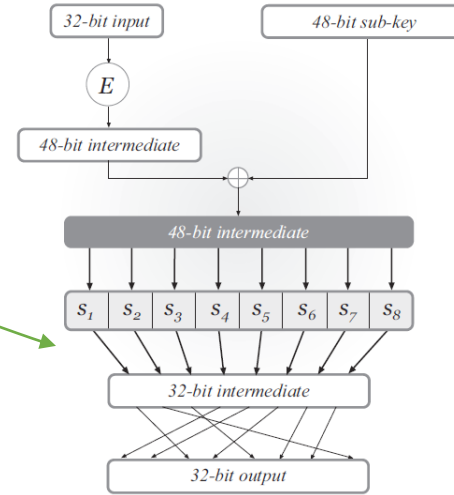

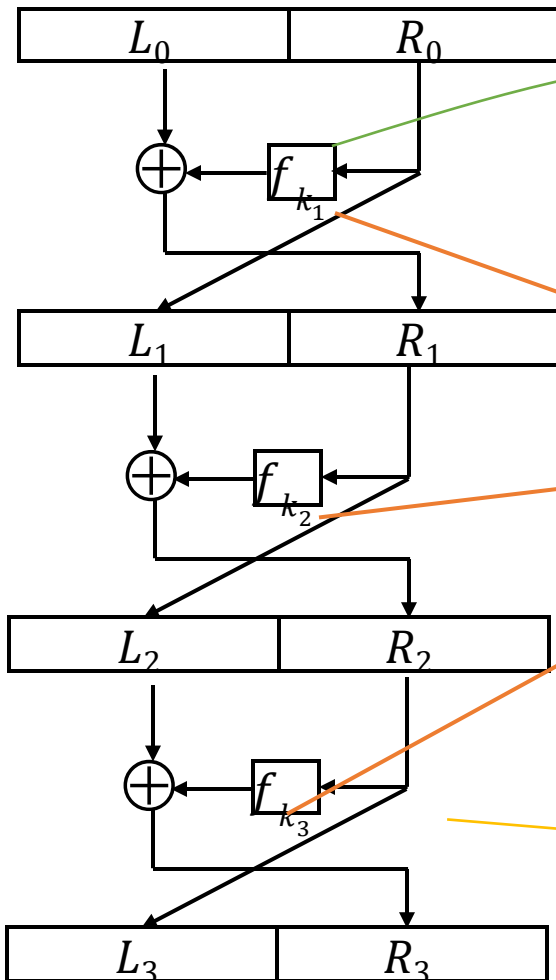

- Developed in 1970 and adopted in 1977
- 56-bit keys and 64-bit block length
- Attacks in  $\approx 2^{56}$  time (too small), security can be upgrade by using triple DES
- 16-round Feistel network
  - Uses the same **mangler function** in each rounds
  - The mangler function is basically an SPN
  - Different sub-keys for each round are derived from the master key

# The DES Mangler Function

- S-boxes are designed such that:
  - Each S-box is 4-to-1
  - Changing 1 bit of input changes at least 2 bits of output
- Mixing permutation and E designed such that:
  - The 4 bits of output from any S-box affect the input to 6 S-boxes in the next round
- Each sub-key is derived by taking certain specific 48 bits from the 56-bit master-key. Where left 24 bits are derived from the left 28 bits of master key and right 24 bits are derived from the right 28 bits of the master key.

# DES Construction

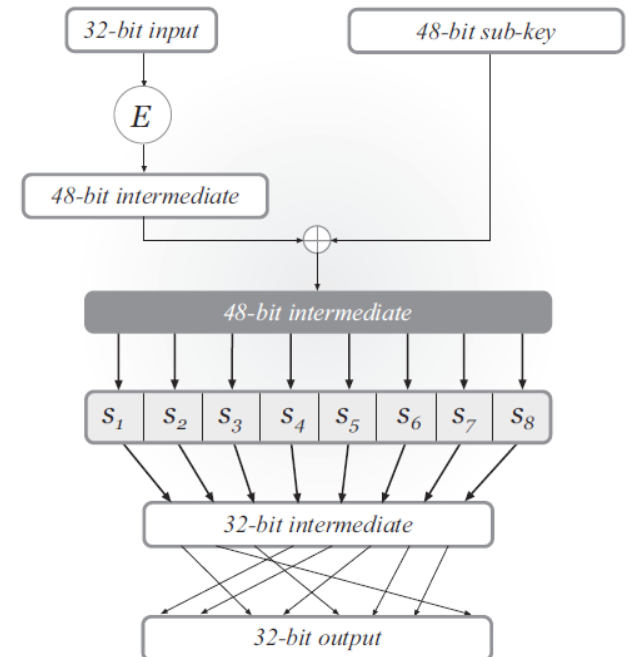

Derived from the 56 bit master key.

Repeated 16 times for Avalanche Effect!

# One round DES: Key recovery Attack

- Observe  $f_{k_1}(R_0) = L_0 \oplus R_1$
- Attack similar to SPN
- Recover  $k_1$  by going over each S-box separately
- Total possibilities of key =  $4^8$ 
  - Using one input/output
- Much smaller than  $2^{48}$

# Two round DES: Key recovery Attack

- Thus,  $f_{k_1}(R_0) = L_0 \oplus L_2$  and  $f_{k_2}(L_2) = R_0 \oplus R_2$
- Obtain  $k_1$  and  $k_2$  as two separate attacks on the DES mangler function.

# More Attacks

- Better than brute-force key-recovery attack for three round DES
- Biham and Shamir gave a  $2^{37}$  time attack given  $2^{47}$  plaintexts (considered not practical)

# Upgrading Security

- Modify DES to work with larger keys!
  - Risky and error prone!
- Build on DES in a **black-box** manner

# Attempt 1: Double DES

- $F'_{k_1, k_2}(x) = F_{k_2}(F_{k_1}(x))$ , where  $k_1$  and  $k_2$  are independent keys
- If best attack on  $F$  takes time  $2^n$ , then does the best attack on  $F^2$  takes time  $2^{2n}$ ?
- No! Still an attack taking  $2^n$  time
  - But, need  $2^n$  memory

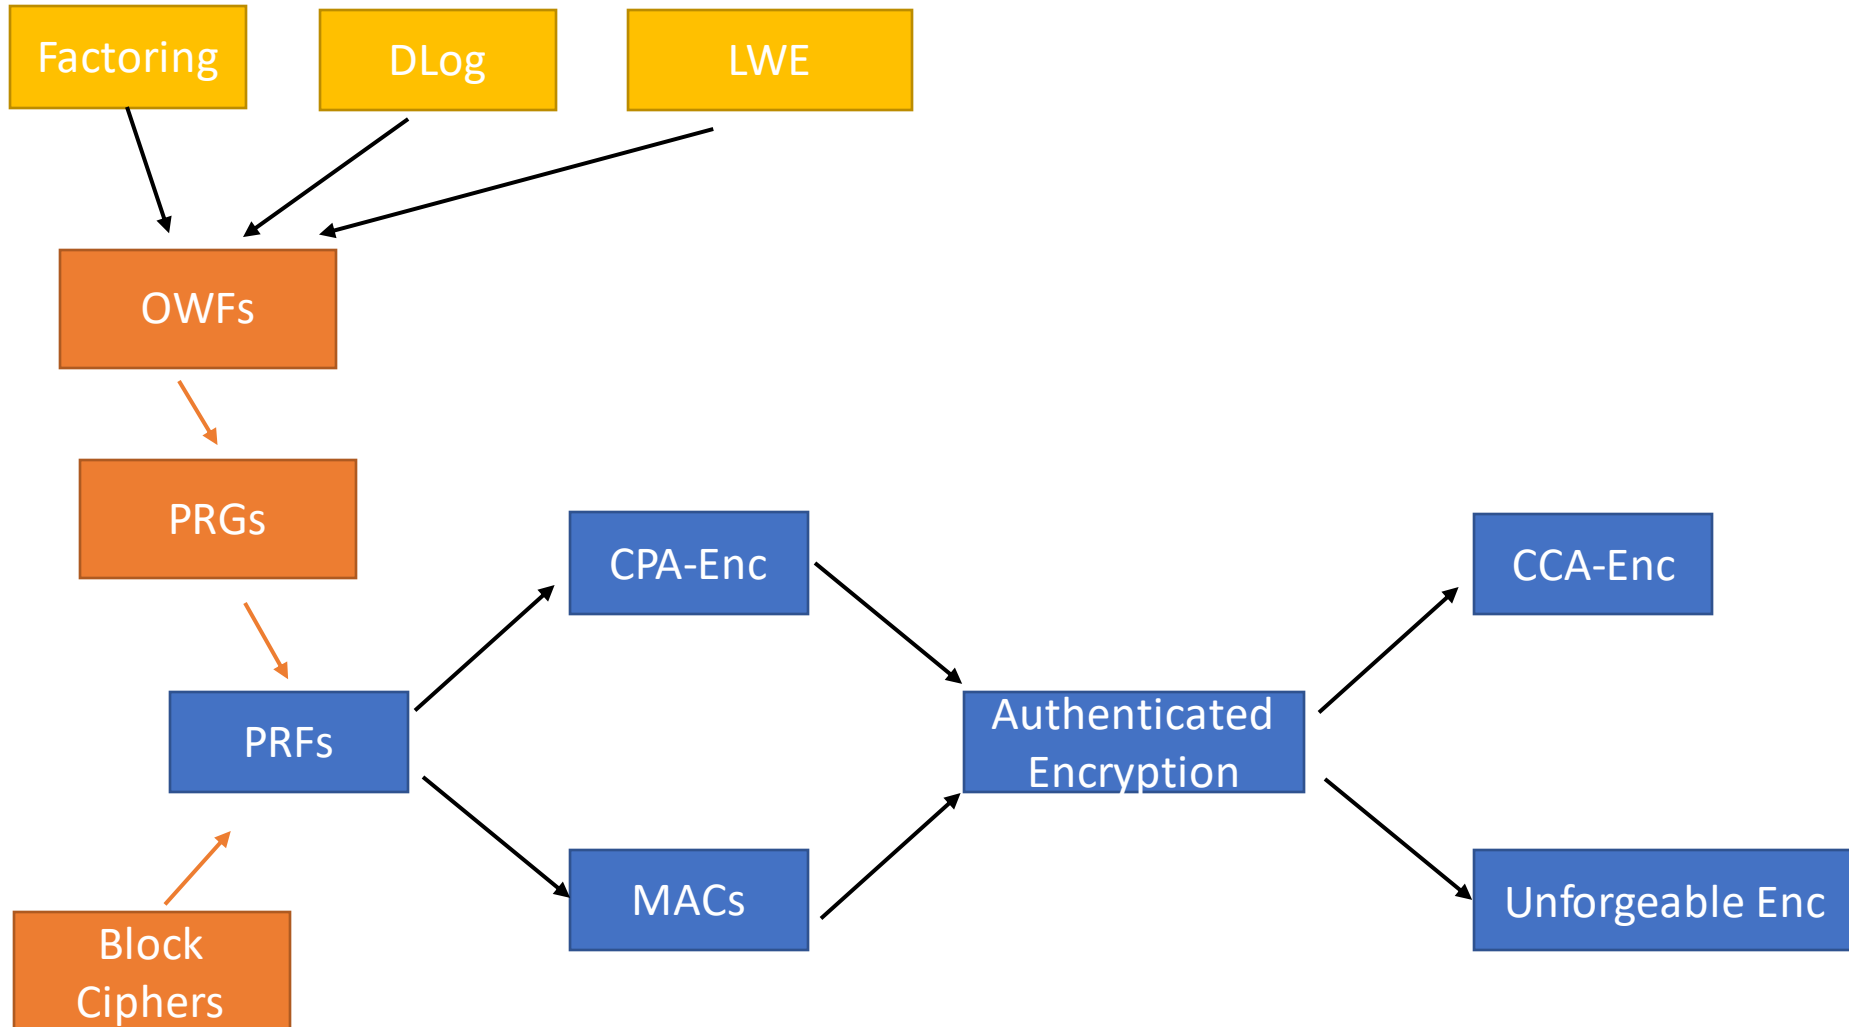

# Attack

- Give  $x, y$  such that  $y = F_{k_2}(F_{k_1}(x))$  we have
$$F_{k_2}^{-1}(y) = F_{k_1}(x)$$
- Exhaustively find all  $k_1, k_2$  such that  $F_{k_2}^{-1}(y) = F_{k_1}(x)$
- Assuming random behavior -  $2^n$  choices
- Test each with another input/output pair.

# Attempt 2: Triple DES

- $F'_{k_1, k_2, k_3}(x) = F_{k_3}(F_{k_2}^{-1}(F_{k_1}(x)))$ , where  $k_1, k_2$  and  $k_3$  are independent keys
- Best attack takes time  $2^{2n}$
- Now, we have AES (winner announced in 2000).
  - Uses the SPN framework
  - Will not cover in class!

# Too Fragile?

Review

# Perfect Security

eav is for  
Eavesdropper

$\text{PrivK}_{A,\Pi}^{\text{eav}}$

1.  $A$  outputs  $m_0, m_1 \in \mathcal{M}$ .
2.  $b \leftarrow \{0,1\}, k \leftarrow \text{Gen}(), c^* \leftarrow \text{Enc}_k(m_b)$
3.  $c^*$  is given to  $A$
4.  $A$  output  $b'$
5. Output 1 if  $b = b'$  and 0 otherwise

Challenge  
ciphertext

Drawback: Large Keys

Encryption scheme  $\Pi = (\text{Gen}, \text{Enc}, \text{Dec})$  with message space  $\mathcal{M}$

is **perfectly indistinguishable** if

$\forall A$  it holds that:

$$\Pr[\text{PrivK}_{A,\Pi}^{\text{eav}} = 1] = \frac{1}{2}$$

$A$  can always succeed with probability  $\frac{1}{2}$ . How?

# CPA-Security

$\text{PrivK}_{A,\Pi}^{\text{CPA}}(n)$

1. Sample  $k \leftarrow \text{Gen}(1^n)$ ,  
 $A^{\text{Enc}_k(\cdot)}$  outputs  
 $m_0, m_1 \in \{0,1\}^*$ ,  $|m_0| = |m_1|$ .
2.  $b \leftarrow \{0,1\}$ ,  $c^* \leftarrow \text{Enc}_k(m_b)$
3.  $c^*$  is given to  $A^{\text{Enc}_k(\cdot)}$
4.  $A^{\text{Enc}_k(\cdot)}$  output  $b'$
5. Output 1 if  $b = b'$  and 0 otherwise

Encryption scheme  $\Pi = (\text{Gen}, \text{Enc}, \text{Dec})$  has **indistinguishable encryptions** under chosen-plaintext attack, or is **CPA-secure** if

$\forall$  PPT  $A$  it holds that:

$$\Pr[\text{PrivK}_{A,\Pi}^{\text{CPA}} = 1] \leq \frac{1}{2} + \text{negl}(n)$$

Only PPT attackers and allowed some failure probability.

# Pseudorandom Function (PRF)

Let  $F: \{0,1\}^* \times \{0,1\}^* \rightarrow \{0,1\}^*$  be an **efficient**, **length-preserving**, **keyed** function.  $F$  is a PRF if for all PPT distinguishers  $D$ , there is a negligible function  $negl(\cdot)$  such that:

$$|\Pr[D^{F_k(\cdot)}(1^n) = 1] - \Pr[D^{f(\cdot)}(1^n) = 1]| \leq negl(n)$$

where  $k \leftarrow U_n$  and  $f \leftarrow Func_n$ .

# CPA secure Encryption

Let  $F$  be a  $PRF: \{0,1\}^n \times \{0,1\}^n \rightarrow \{0,1\}^n$ .

- $Gen(1^n)$ : Choose uniform  $k \in \{0,1\}^n$  and output it as the key
- $Enc_k(m)$ : On input a message  $m \in \{0,1\}^n$ , sample  $r \leftarrow U_n$  output the ciphertext  $c$  as
$$c := \langle r, F_k(r) \oplus m \rangle$$
- $Dec_k(c)$ : On input a ciphertext  $c = \langle r, s \rangle$  output the message
$$m := F_k(r) \oplus s$$

Encryption scheme is  
randomized!

# CCA-Security

$\text{PrivK}_{A,\Pi}^{\text{CCA}}(n)$

1. Sample  $k \leftarrow \text{Gen}(1^n)$ ,  
 $A^{Enc_k(\cdot), Dec_k(\cdot)}$  outputs  
 $m_0, m_1 \in \{0,1\}^*$ ,  $|m_0| = |m_1|$ .
2.  $b \leftarrow \{0,1\}$ ,  $c^* \leftarrow$   
 $Enc_k(m_b)$
3.  $c^*$  is given  $A^{Enc_k(\cdot), Dec_k(\cdot)}$
4.  $A^{Enc_k(\cdot), Dec_k(\cdot)}$  (query not  
allowed on  $c^*$ ) output  $b'$
5. Output 1 if  $b = b'$  and 0  
otherwise

Encryption scheme  $\Pi =$   
 $(Gen, Enc, Dec)$  has  
indistinguishable encryptions  
under ciphertext attack, or is  
CCA-secure if

$\forall$  PPT  $A$  it holds that:

$$\Pr[\text{PrivK}_{A,\Pi}^{\text{CCA}} = 1] \leq \frac{1}{2} + \text{negl}(n)$$

Will construct in a few  
lectures!

Good Luck!

Thank You!
